2587. EFFECT OF γ -RAYS ON THE PHYSICO-CHEMICAL PROPERTIES OF ERYTHROCYTES (Russian text) - Kriger Y. A. and Elhovskaya E. S. - BIOFIZIKA 1958, 3/6 (711-716) Graphs 3 illus. 3

Gamma-irradiation (42 kr., 700 r. per min.) followed by incubation causes an increase of low-frequency resistance in human erythrocytes; this demonstrates the swelling of the stromocytes with preservation of their structure. The data were confirmed in electron-microscopic investigations: no considerable changes were revealed in the structure of the stroma of the irradiated erythrocytes. Gamma-irradiation with 84 kr. led to an insignificant low-frequency electroconductivity, related to certain infractions of the submicroscopic structure of the erythrocytes; this was also confirmed in electron microscopy. Without a following incubation, irradiation of the erythrocytes causes an increase of ion migration out of the latter into the electrolyte-free medium as compared with the ion migration in control cells not having been submitted to haemolysis. The formation of a suspension of the irradiated erythrocytes in distilled water causes a gradual decrease of their low frequency-resistance, i.e. a phenomenon similar to stromoporosis. Electron-microscopic studies confirmed the conclusions based on conductivity measurements in demonstrating craters or holes, uncovered fibrillar structures and the falling off of whole pieces of the irradiated and then destroyed erythrocytes. Taken as a whole, the data raise doubts as to the validity of Fall's hypothesis, according to which the mechanisms of hypotonic and radiation haemolysis are identical. The latter is evidently based on such a weakening of the bonds between the separate components of the structure of the erythrocyte that a succeeding injuring effect provokes sharp infraction.

TITLE: Automatic Welder for Assembly and Welding of Reinforcements
(Avtomat dlya sborki i svarki armaturnykh setok)

PERIODICAL: Stroit. materialy, 1957, Nr 7, p 17

ABSTRACT: Report on an automatic machine designed by P.I. Beletskiy, electrician and machinist, designed to weld reinforcements up to 4.5 m wide. The machine consists of a base along which a carriage carrying the welder proper moves, the latter consisting of a 75 kva welding transformer and panels bearing 4 portable electrodes. The system permits simultaneous welding of 4 spots on bars up to 12 mm in diameter and 2 spots on bars over 12 mm, the total thickness of the bars being ≤ 32 mm. The spacing between longitudinal rods may be 85-300 mm and between transverse rods 85-250 mm. Application of force to the electrodes is electromechanical; a force of up to 500 kg is developed. The speed of longitudinal motion of the assembled reinforcement is 8 m/min. The rate of motion of the welding carriage is 12 m/min. The power of the drive motor is 3.7 kva.

TITLE: The use of wire-type resistance strain gauges for tests in a vacuum

SOURCE: Novy*ye mashiny*i pribory* dlya ispy*taniya metallov. Sbornik statey. Moscow, Metallurgizdat, 1963, 92-93

TOPIC TAGS: strain gauge, wire type strain gauge, resistance strain gauge, metal testing, vacuum strain testing

ABSTRACT: Using the Wheatstone bridge arrangement shown in Fig. 1 of the Enclosure, which can be balanced by the deflection of a cantilever, the author discovered that, contrary to expectations, the imposition of a vacuum alters the electrical resistance and coefficient of strain sensitivity of a resistance strain gauge, resulting in displacement of the zero point and erroneous force measurements. Experiments showed that these effects are probably due to the formation of an air cushion between the strain gauge and the metal surface during evacuation, as well as to the changes in elasticity and adherence resulting from the abrupt decrease in humidity. A technique for eliminating these errors is also described, consisting of heating the sample and strain gauge to

TITLE: Vacuum tribometer

PERIODICAL: Zavodskaya laboratoriya, v. 29, no. 2, 1963, 227 - 229

TEXT: A tribometer is described which differs from the ordinary types in that the friction strength is measured by means of wire strain gauges in a vacuum chamber and that the temperature can be varied between -70 and +100°C by a copper block with channels through which flow the cooling or heating liquids. The rate of feed can be varied between 10^{-3} and 10^2 mm/min. The maximum error of measurement was 3%. The friction coefficient can be determined in vacuo at 10^{-5} mm Hg or in inert gas. It was found for LKC-30 (SKS-30) rubber that below 15°C the friction coefficient measured in vacuo differs considerably from that measured in air because the coefficient of friction in air has been assumed too low; presumably owing to the condensation of water vapor on the friction surface. There are 2 figures.

TITLE: The friction coefficient of rubber

PERIODICAL: Kauchuk i rezina, no. 3, 1963, 20 - 22

TEXT: The friction coefficient of rubber is defined as the main characteristic in calculating the friction properties of parts and machine units; in engineering practice it is the ratio of friction force F to the normal load N : $\mu = \frac{F}{N}$. The magnitude of the nominal surface of contact parts is not taken into account. The effect of the nominal contact surface on the friction coefficient of rubber is studied, measured at $N = \text{const}$, and $p = \text{const}$ (nominal pressure - $p = N/S_n$). Conclusion: the friction coefficient measured at $N = \text{const}$ depends on the nominal contact surface; measured at $p = \text{const}$ it does not depend on it. Experiments have confirmed this conclusion. The friction coefficient was measured on a tribometer instrument (Figure 1) based on the idea that the contact surface changes simultaneously with a change of the load, whereby the pressure

Card 1/3

The friction coefficient of rubber

S/138/63/000/003/006/008
A051/A126

remains constant. For materials of various hardness, a different change in the friction coefficient is noted depending on the nominal contact surface. It is generally concluded that, when using the friction coefficient for calculating parts and evaluating their friction properties, it is necessary to consider that the friction coefficient determined according to ГОСТ-426-57 (ГОСТ-426-57) is only a relative value, since it depends on the magnitude of nominal contact surface and nominal load. At a constant normal pressure, the friction coefficient is actually a constant value for various nominal contact surfaces and can be used in calculating constructions only for normal pressures where it has been measured. In other normal pressures, it can be calculated from the law of rubber friction. There are 2 figures and 1 table.

TITLE: Effects of lubricants on friction of rubber on metal at low temperatures

SOURCE: AN SSSR. Nauchnyy sovet po treniyu i smazkam. Teoriya smazochnogo deystviya i novyye materialy (Theory of lubricating action and new materials). Moscow, Izd-vo Nauka, 1965, 72-75

TOPIC TAGS: rubber, friction, lubricant, low temperature effect, low temperature research/ TsIATIM 221 lubricant, TsIATIM 205 lubricant

ABSTRACT: The effects of solid lubricants (fine dispersion graphite type KT and molybdenum disulfide), liquid lubricant No. 3, and lubricants TsIATIM-221 (based on No. 3) and TsIATIM-205 on the maximum friction between various rubbers and steel were investigated in the temperature range 50 to -200C at a constant load of 2 kg/mm², contact area 1.5 cm², and sliding speed 1 mm/min on the apparatus described by G. M. Bartenev, V. V. Lavrent'yev, and A. I. El'kin (Priboiy dlya issledovaniya sily treniya vysokoelelasticheskikh polimerov. Teoriya treniya i iznosa. Izd-vo "Nauka," 1965). The unlubricated friction force of unfilled rubber (based on SKF-26) on steel was found to increase slowly from 4.5 kg at 20C

Card 1/3

2
to 5 kg at -30C, drop sharply to \approx 1 kg at that temperature, and remain approximately constant to temperatures of -200C. Graphite lubrication decreased the friction force to \approx 0.6 kg (almost constant from 20 to -200C), while molybdenum disulfide was 15-20% less effective than graphite. The friction force for unfilled rubber (based on SKMS-10) on steel without lubrication was found to be larger than with liquid lubrication over a range of temperatures (depending on the lubricant) and was smaller over other temperature ranges (see Fig. 1 on the Enclosure). ABSTRACT: Frictional properties of rubber-like polymers (unfilled rubbers made from natural latex, butadiene, and other synthetic latexes) were investigated with a vacuum tribometer as explained by G. M. Bartenev and A. I. Yel'kin (Zavodskaya laboratoriya, 1963, No. 2). The friction forces between the specimen and a polished steel surface (13 class finish) were measured over a temperature range of 100 to -200C and in the velocity range of 10^{-3} - 10^{-2} mm/minute. Test results (see Figs. 1 and 2) show that the two curves are essentially mirror images.

K. A. Grosch (Nature, 197, March 2, 858, 1963) and other authors have tried to correlate the maximum friction with the maximum mechanical losses in the rubber, considering the friction process as dissipation of elastic energy in the rubber volume due to, for example, vibrations induced by surface roughness. According to the theory of G. M. Bartenev (K teorii sukhogo treniya. Dokl. AN SSSR, 1954, t. 96, 1161) and some experimental data, the adhesion mechanism of friction (loss at surface due to bending and breaking of polymer chains) is of greater importance for friction on a polished surface than the elastic loss mechanism. A qualitative

L 1937-66

ACC NR: AT5022668

Fig. 2. Generalized friction-speed curve for SKS-50 (at 40°C, load = 0.65 kg/cm²)

explanation of the shape of the curves in Fig. 1 is presented which stipulates that the maximum friction force cannot be correlated with the experimental results if elastic losses are assumed but that the maximum is primarily related to the rubber transition temperature below which solidification reduces the actual contact area and thus the friction. Orig. art. has: 3 figures and 1 formula.

 TITLE: Effect of alloying on the structure and properties of Mg-Li alloys containing aluminum
 SOURCE: Tsvetnyye metally, no. 6, 1966, 83-85
 TOPIC TAGS: magnesium alloy, lithium containing alloy, aluminum containing alloy, tin containing alloy, silver containing alloy, copper containing alloy, nickel containing alloy, calcium containing alloy, barium containing alloy, bismuth containing alloy, neodymium containing alloy, alloy property
 ABSTRACT: An attempt has been made to improve and stabilize the mechanical properties of Mg-14% Li-1.5% Al alloy by additional alloying with Ce, Bi, Ba, Ni, Nd, Co, La, Cu, Sn and Ag. Highly machined alloy ingots were extruded at 200C with a reduction of 88% and tested for structure and mechanical properties. The test results showed that the structure of cast Mg-14% Li-1.5% Al alloy had a coarse-grained δ -phase, which partly recrystallized with extrusion. The majority of quaternary alloys in the as-cast condition had a finer structure than the ternary alloys, while extruded alloys had a partly recrystallized structure with precipitation of a secondary phase.

With increasing content of Ca, Bi, Ba, Ni, Nd, Ce, La, Cu (from 0.10—0.30 to 1.5—2.0%), the tensile strength of the ternary alloys decreased by 7—9 kg/mm² and the ductility increased by 2—3 times (see Fig. 1). Alloying Mg—14%Li—1.5%Al with silver decreased the strength of the alloy considerably less than the other elements and had practically no effect on the structure. Mechanical tests of extruded alloys after stabilization annealing showed that none of the alloying elements, except silver, improves the stability of the mechanical properties. After stabilizing annealing (100 hr at 60C) the Mg—14%Li—1.5%Al—2%Ag alloy had a tensile strength of 17 kg/mm², a yield strength of 15.8 kg/mm², and an elongation of 24%, compared to 15.5 kg/mm², 14.8 kg/mm² and 20%, respectively, for Mg—14%Li—1.5%Al alloy, and showed at 60C a 15—20% increase in the short-and long-term hardness.  TITLE: Effect of additional alloying on the structure and properties of beta-phase magnesium-lithium alloys
 SOURCE: AN SSSR. Izvestiya. Metally, no. 5, 1966, 125-131
 TOPIC TAGS: magnesium lithium alloy, aluminum containing alloy, zinc containing alloy, copper containing alloy, rare metal containing alloy, silver containing alloy, alloy structure, alloy property, *MAGNESIUM BASE ALLOY, LITHIUM CONTAINING ALLOY, SOLID MECHANICAL PROPERTY*
 ABSTRACT: The effect of lithium and some other alloying elements on the structure and properties of magnesium-base alloys has been investigated. It was found that the mechanical properties of binary magnesium-lithium alloy remain unchanged with lithium content varied within 10—20%. The hot extruded alloys have high ductility, 40—50% elongation, but a tensile strength of only 9—11 kg/mm² and a yield strength of 6—7 kg/mm². In the as-cast condition, the alloy has a uniform coarse-grained structure of solid solution with grain size decreasing as lithium content increases from 10% to 20%. Aluminum added in the amount of 1.5% to magnesium-14% lithium alloy raises the tensile strength to 22—23 kg/mm², the yield strength to 20—22 kg/mm², and the hardness to 60—70 kg/mm², but reduces elongation to 10—15%; zinc, silver, copper
 Card 1/2 UDC: 669.721.5'884

L 46768-66

ACC NR: AP6031721

cadmium, and neodymium also increase the tensile and yield strength, but not as much as aluminum. Zinc, for instance, added in the amount of 0.25—4.0%, increases the alloy strength by 5—6 kg/mm², but reduces the elongation from 40—50% to 30—35%. Addition of 0.5—5.0% silver increases the alloy strength, but somewhat lowers its ductility. The alloy containing 14% lithium and 5% silver had a tensile strength, yield strength and elongation of 14 kg/mm², 10.7 kg/mm², and 38%, respectively. Alloying with neodymium, lanthanum and cerium increased the elongation to 60% without significant effect on the strength. Aging at 20C for 6 months or at 60C for 100 hr lowers the strength and raises the ductility of alloy containing aluminum. Alloys with an aluminum content of 0.75—2.0% are the least affected by aging. Zinc, silver, copper, neodymium, lanthanum, zirconium and yttrium reduce somewhat the softening effect of aging. Orig. art. has: 5 figures. [ND]

1. The purpose of this report is to provide information on the operation of the system as a whole and on the individual components thereof. The system is a computerized system for the processing of data. It is designed to handle a large volume of data and to provide a high degree of accuracy in the results. The system is composed of a number of components, including a central processing unit, a memory unit, and a control unit. The central processing unit is the heart of the system and is responsible for the execution of the program. The memory unit is used to store the data and the program. The control unit is responsible for the coordination of the various components of the system. The system is designed to be flexible and to be able to handle a wide range of data. It is also designed to be reliable and to provide accurate results. The system is currently being used for the processing of data and is expected to continue to be used for some time to come.

TITLE: Transformation of Fluctuations of Amplitude and Phase of Self-Oscillations by Resonant Systems (O preobrazovanii flyuktuatsiy amplitudy i fazy avtokolebaniy rezonansnymi sistemami)

PERIODICAL: Radiotekhnika i Elektronika, 1957, Vol 2, Nr 1, pp 28-33 (USSR)

ABSTRACT: The authors describe a theoretical investigation of the transmission of a signal with random fluctuating phase and amplitude by a system which includes a linear (resonant) element and a nonlinear (detector) element. Formulas are derived which allow determination of the statistical characteristics of the output phase and amplitude of a resonant system if the statistical characteristics of the input phase and amplitude fluctuations are known. The problem has dual interest: (1) fluctuation phenomena are important in the shf generators; amplitude and phase of fluctuations can be measured by a circuit resembling that of Bershteyn; (2) in designing oscillators with automatic frequency control, it is necessary to know the spectra of fluctuations. On the basis of a differential equation connecting the input and the output processes, the authors develop a set of linear truncated equations which approximately

Card 1/2

109-2-1-4/17

Transformation of Fluctuations of Amplitude and Phase of Self-Oscillations by ...

demonstrate that the fluctuations of the output amplitude and phase are lagging behind the fluctuations of the input amplitude and phase. If the spectra of the input process are known, the spectra of the output phase difference and amplitude can be determined by the use of the above-developed equations. Assuming that amplitude fluctuations of an oscillator do not cause its frequency fluctuations, the natural fluctuations of phase and amplitude which are due to schrot effect and thermal noise are statistically independent and are described by formulas (26) and (27). The natural width of the spectrum of an oscillator can be determined by means of formula (31). Instability of the parameters of an oscillator determines the "technical" width of the spectrum of self-oscillations (formulas given). In a real physical oscillator, the technical drift and the natural fluctuation are combined as two statistically independent processes.

There are two figures and nine references, three of which are Soviet, in the article.

TITLE: Phase-lock Automatic Frequency Control of Klystrons by
means of a Molecular Oscillator (Fazovaya avtopodstroyka
klistrona po moléulyarnomu generatoru)

PERIODICAL: Radiotekhnika i Elektronika, 1957, Vol.II, No.10,
p. 1300 (USSR).

ABSTRACT: The frequency of a 2.5 cm, 10 mW klystron was stabilised
by means of a molecular oscillator. A second harmonic of the
klystron and the signal of the molecular oscillator were applied
to a balanced mixer and the resulting difference-frequency
signal was applied to a phase detector. A signal from a quartz
stabilised oscillator, operating at 50 Mc/s, was also fed to
the detector. The output voltage of the detector was applied to
the reflector of the klystron, as a result of which the klystron
had a pull-in bandwidth of 0.15 Mc/s and a synchronisation
bandwidth of 0.5 Mc/s. There are 6 references, 5 of which are
Slavic.

TITLE: Reproducibility of the frequency of a molecular generator on the ammonia transition line

SOURCE: USSR. Komitet standartov, mor i izmeritel'nykh priborov. Trudy institutov Komiteta, no. 77(137), 1965. Issledovaniya v oblasti izmereniya vremeni i chastoty (Research in the field of time and frequency measurement), 67-71

TOPIC TAGS: molecular generator, crystal oscillator, klystron, electron tube, frequency characteristic, mean square error

ABSTRACT: The possibility of using a molecular generator with an ammonia NH_3 emission line in the time and frequency service is examined. The work was done at VNIIFTRI to check the frequency of the standard 100-kHz quartz-crystal oscillators. The voltage from the quartz-crystal oscillator is fed to a frequency multiplier (see Fig. 1), where it is multiplied by 2560 and by 31. The frequencies of the oscillators are connected by the relation

$$f_1 = \frac{f_2 - F}{23870}$$

where f_1 is the frequency of the quartz-crystal oscillator; f_2 the frequency of the
